# INTRODUCTION

The Philippine Health Insurance Corporation (PhilHealth) has been implementing the Electronic Claims (eClaims) System since 2016 for the All Case Rates (ACR) provider payment mechanism. This system was developed to automate the claims process, enabling improved turnaround times for claims processing and reimbursement of providers. Despite notable improvements in the efficiency of claims processing, there exists continued delays in turnaround time, and high numbers of “Return-to-Hospital” claims. These can be mainly attributed to the existence of manual procedures in the claims process, including the adjudication of claims, and the lack of front-end claims data validation mechanisms.

The Universal Health Care Act of 2019 aims to address these issues by mandating PhilHealth to shift to paying providers prospectively using Diagnosis-Related Groups (DRG). A key component of this reform is an enhanced version of the current eClaims system which accommodates the collection of data required for DRG grouping.

This guide is designed to provide in-house hospital developers and service providers essential insights and instructions on how to successfully navigate the electronic claims submission process within the context of the PhilHealth DRG system.

# APPLICATION PROGRAM INTERFACE (API)

The Application Programming Interface (API) of the PhilHealth e-Claims Web Service (PECWS) serves as the primary interface for interactions with PhilHealth's electronic claims processing system. This existing facade API is the gateway through which healthcare institutions and service providers can connect to and communicate with PhilHealth's infrastructure for the purpose of submitting electronic claims.

It acts as the bridge, allowing these entities to send claim-related data and information to PhilHealth, enabling the processing and evaluation of healthcare claims. Through the PECWS API, users can submit data regarding patient information, medical procedures, diagnoses, and other relevant details necessary for the billing and reimbursement of healthcare services.

# WEB SERVICE METHODS

## 1. Get Token Method

This method will generate a token as authorization key to access API methods using the encrypted Accreditation Number and Software Certification ID of the health facility.

### Endpoint

`https://{pecws.domain}/PHIC/Claims3.0/getToken`

### Method

GET

### Inputs

#### Header

Key	Value/Remarks
<b>accreditationNo</b>	The PhilHealth Accreditation Number (PAN) of the Health Facility
<b>softwareCertificateId</b>	The software certification ID for PECWS 3.0 of the Health Facility

### Output

JSON object containing the following key-value pairs:

Key	Value/Remarks
<b>success</b>	A value of 'true' that data has been retrieved successfully
<b>message</b>	If an error was encountered during the execution of this method, this will contain the error message
<b>result</b>	The generated Token

#### Sample Output Payload

```
{
  "message": "Token is valid for 20 seconds",
  "result": "eyJhbGciOiJIUzI1NiB1IjogbnVlcnQs",
  "success": true
}
```

## 2. Validate eSOA Method

A method that will validate encrypted eSOA XML format against Document Type Definition (DTD), data format and valid values set by PhilHealth.

### ¶Important Note:

After successful validation, eSOA XML should be encrypted using PhilHealth Public Key and submitted as attachment to electronic claims using the **EclaimsUpload Method**.

## Endpoint

`https://{pecws.domain}/PHIC/Claims3.0/validateeSOA`

## Method

POST

## Inputs

### Header

Key	Values
<b>token</b>	PECWS authentication token

### Body

The eSOA XML must be encrypted using the cipher key issued by PhilHealth to the Health Facility. The encrypted text contains the following key-value pairs.

Key	Value/Remarks
<b>docMimeType</b>	"text/xml"
<b>hash</b>	The computed hash value of the unencrypted text.
<b>key1</b>	"" (Empty string)
<b>key2</b>	"" (Empty string)
<b>iv</b>	The initialization vector used in the AES encryption
<b>doc</b>	The result of the encryption of eSOA XML text using the cipher key of the HF

This method can be used by the health facilities in transmitting electronic claims (eClaims) file to PhilHealth. This method checks for DTD compliance and validates the values of the XML element attributes if they are valid based on eClaims XML Elements Attribute Definition table.

The transmission date will be the official date received for the uploaded claims upon which the Turn- around Time (TAT) will be measured.

### Endpoint

`https://{pecws.domain}/PHIC/Claims3.0/uploadeClaims`

### Method

POST

## 7. Search Case Rates Method

A method that allows the caller to search for the case rate amounts with different applicable periods for target benefit packages.

### Endpoint

`https://{pecws.domain}/PHIC/Claims3.0/searchCaseRates`

### Method

POST

### Inputs

#### Header

Key	Value
<b>token</b>	PECWS authentication token

#### Body

The JSON object contains the following key-value pairs:

Name	Values
<b>icdcode</b>	The ICD code of the target benefit package
<b>rvscode</b>	The RVS code of the target benefit package
<b>description</b>	Substring or full text of the name or description of the target benefit packages
<b>targetdate</b>	Format: mm-dd-yyyy. If this parameter has a valid date value (which, normally the admission date of a target claim), this method will return only the record for the applicable period that covers the target date. If an empty string is passed as the value is passed of this parameter, all the applicable periods of the target benefit packages will be returned

## Input Payload

```
{  
  "icdcode": "",  
  "rvscode": "",  
  "description": "DENGUE",  
  "targetdate": "02-14-2024"  
}
```

## Output

This method returns a JSON object with the key-value pairs described below:

## Guidelines for the Data Encryption Using the Cipher Key of the Health Facility

Data will be encrypted using AES-256-CBC algorithm. PhilHealth issues a *cipher key* to the health facility for each certified software. The cipher key is to be used in generating the secret key for the AES encryption. System developers of service providers/health facilities may use their preferred programming language and tools for the data encryption/decryption.

```
{
  "docMimeType": "{MIME type of the data}",
  "hash": "{SHA-256 hash of the data before encryption}",
  "key1": "",
  "key2": "",
  "iv": "{The initialization vector encoded as base-64 string}",
  "doc": "{The encrypted data encoded as base-64 string}"
}
```

Figure 1: Sample Format/Layout of the Resulting Encrypted Data

1. Get the hash total of the data to be decrypted using SHA-256 hash algorithm. After decrypting the data, a new hash total can be computed using the same algorithm, which can then be compared to the original hash total generated before decryption. If the two hash totals match, the data integrity is preserved. However, if the hash totals do not match, the data may have been tampered with or corrupted during decryption.
2. Set the value of the secret key to be used for the AES encryption.
  - a. Hash the given cipher key using SHA-256 algorithm.
  - b. Use the first 32 bytes of the resulting hash value as the passphrase for the AES encryption.
  - c. If the length of the resulting hash value is less than 32 bytes, pad the hash value with null character (with hexadecimal value of '0x00') to have a value having 32 bytes.
3. Prepare the initialization vector (IV) to be used
  - a. Generate an array of random 16 bytes (for a total of 128 bits).
  - b. Encode the array of bytes as base 64 string
4. Encrypt the data
  - a. Convert the data as array of bytes
  - b. Encrypt the data using AES encryption using the values the array of bytes of the password, the IV and the data.
  - c. Encode the resulting encrypted array of bytes as base-64 string.

5. Build the JSON string of the encrypted data using the following names and their corresponding values:
- a. **docMimeType**: The value for this key will be the MIME type of the target data. For example, if the target data is a string in JSON format, the value for this key should be “application/json”.
  - b. **hash**: Use the resulting value of Step #1 as the value of this key
  - c. **key1**: Set the value of this key as empty string.
  - d. **key2**: Set the value as empty string.
  - e. **iv**: Use the resulting value of Step #3.b as the value of this key
  - f. **doc**: Use the resulting value of Step #4.c as the value of this key
